Semantic Analysis

Martin Rinard

Laboratory for Computer Science
Massachusetts Institute of Technology

Error Issue

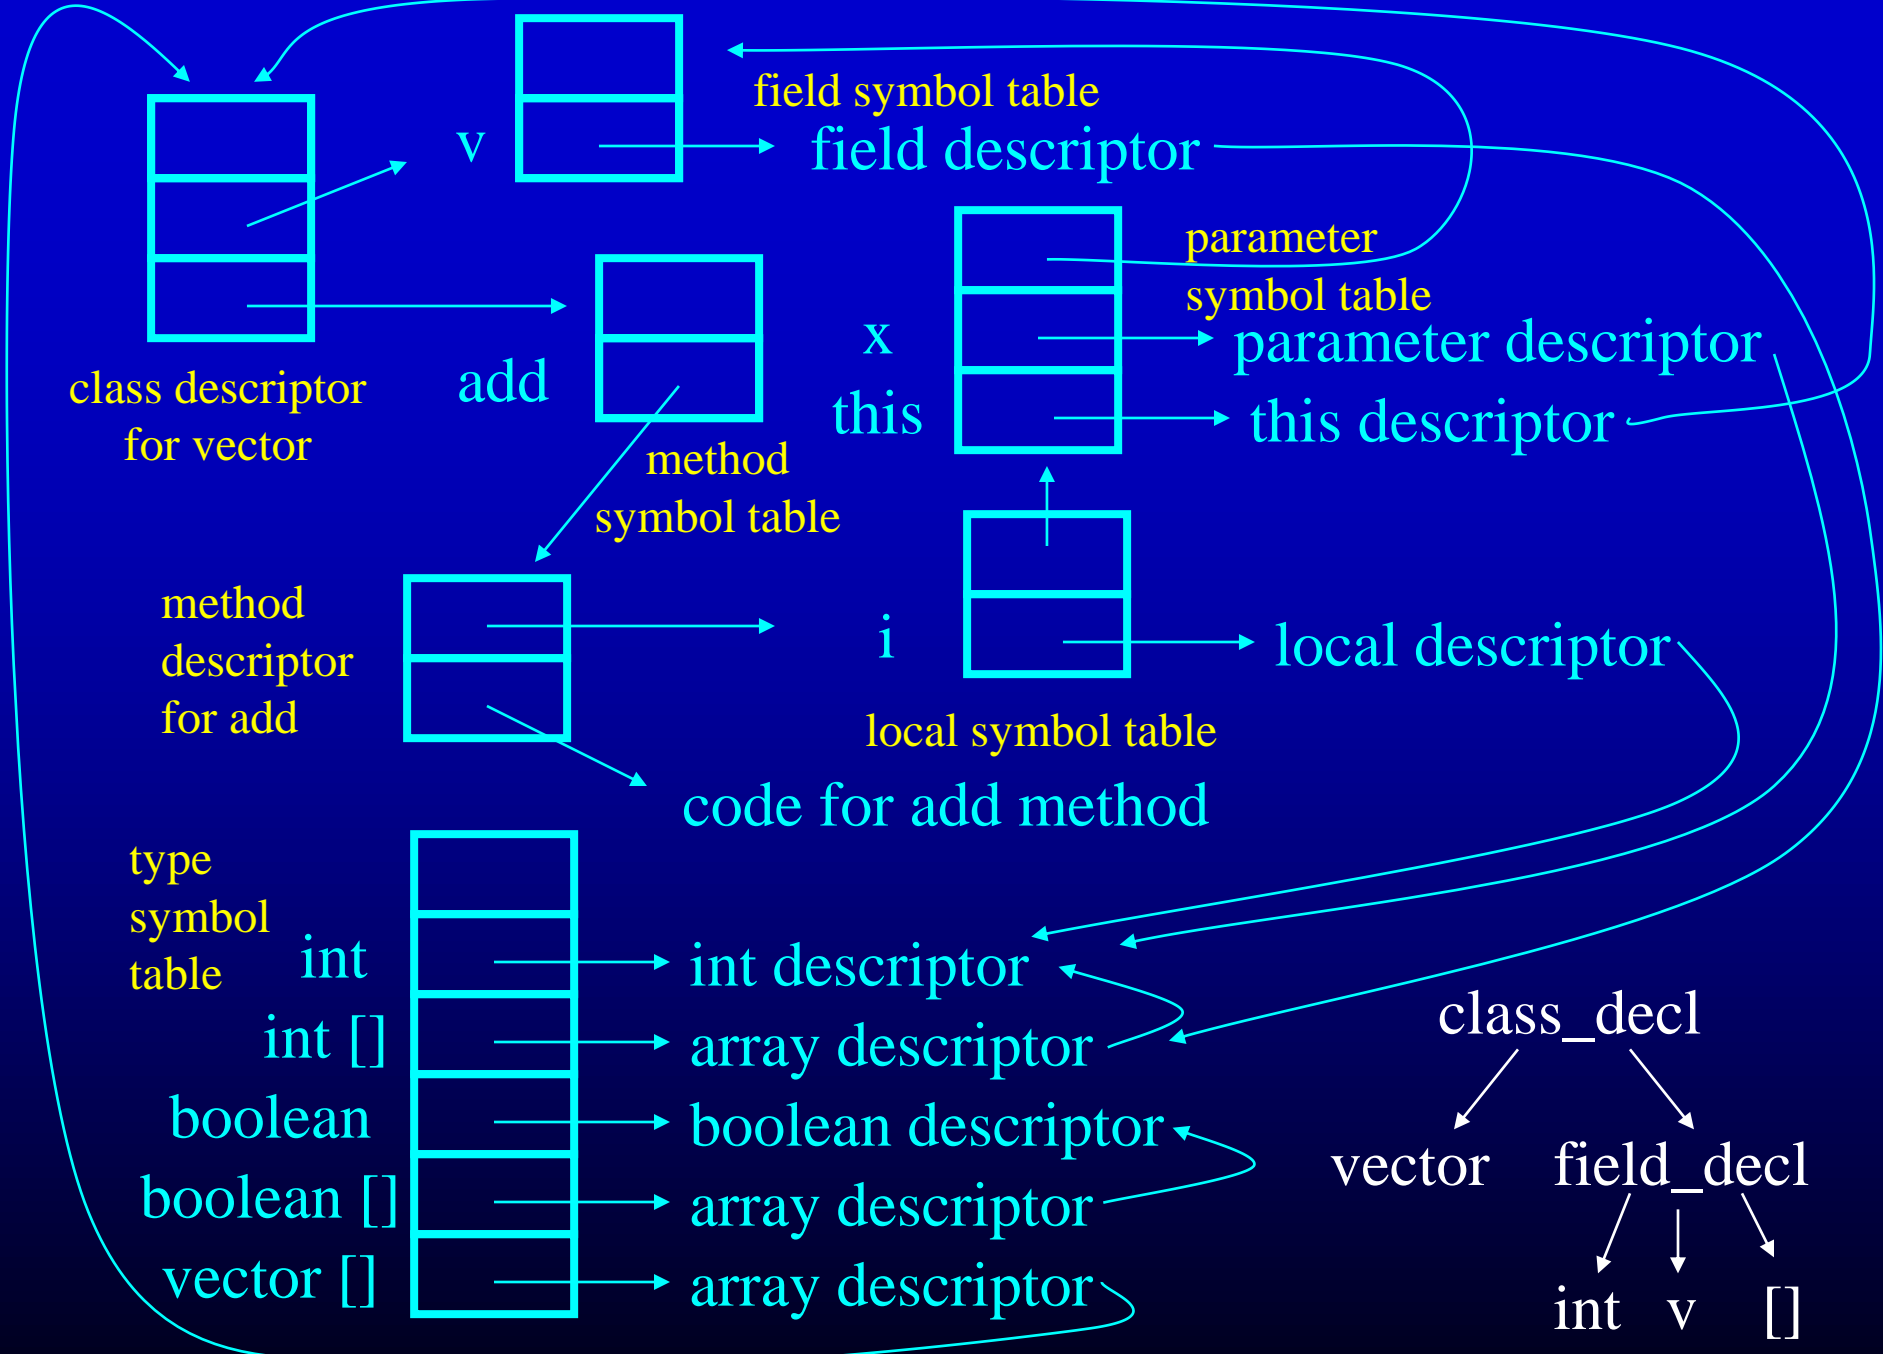

- Have assumed no problems in building IR
- But are many static checks that need to be done as part of translation
- Called Semantic Analysis

Goal of Semantic Analysis

- Ensure that program obeys certain kinds of sanity checks
 - all used variables are defined
 - types are used correctly
 - method calls have correct number and types of parameters and return value
- Checked when build IR
- Driven by symbol tables

Symbol Table Summary

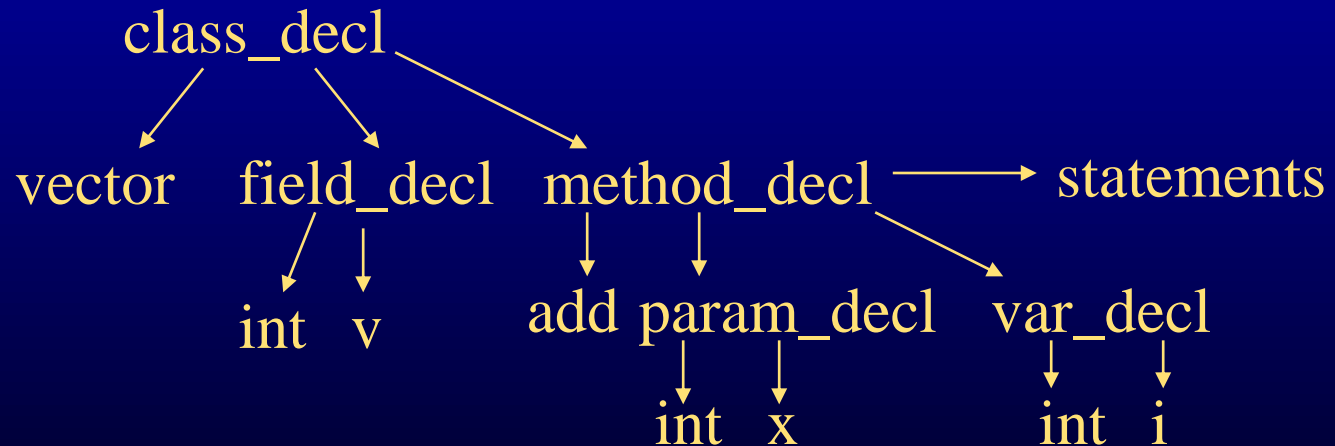

- Program Symbol Table (Class Descriptors)
- Class Descriptors
 - Field Symbol Table (Field Descriptors)
 - Field Symbol Table for SuperClass
 - Method Symbol Table (Method Descriptors)
 - Method Symbol Table for Superclass
- Method Descriptors
 - Local Variable Symbol Table (Local Variable Descriptors)
 - Parameter Symbol Table (Parameter Descriptors)
 - Field Symbol Table of Receiver Class
- Local, Parameter and Field Descriptors
 - Type Descriptors in Type Symbol Table or Class Descriptors

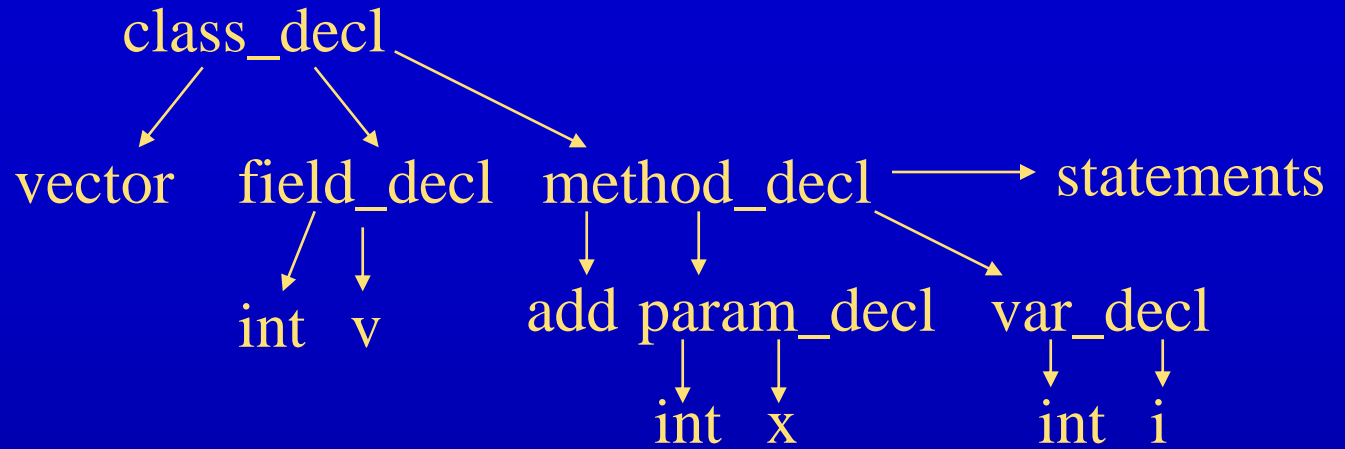

Translating from Abstract Syntax Trees to Symbol Tables

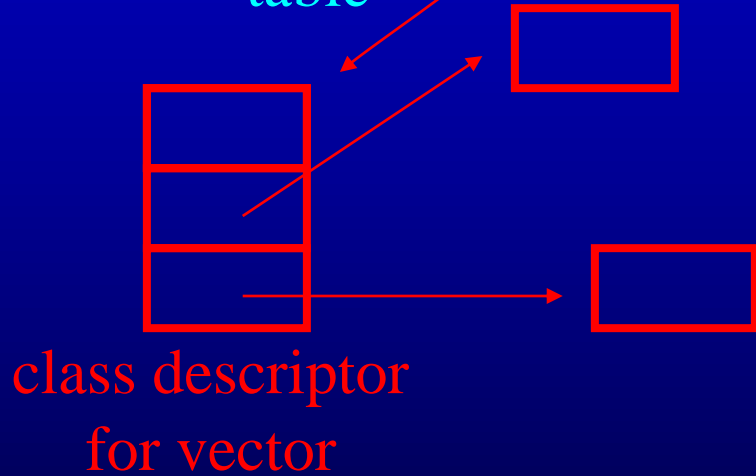

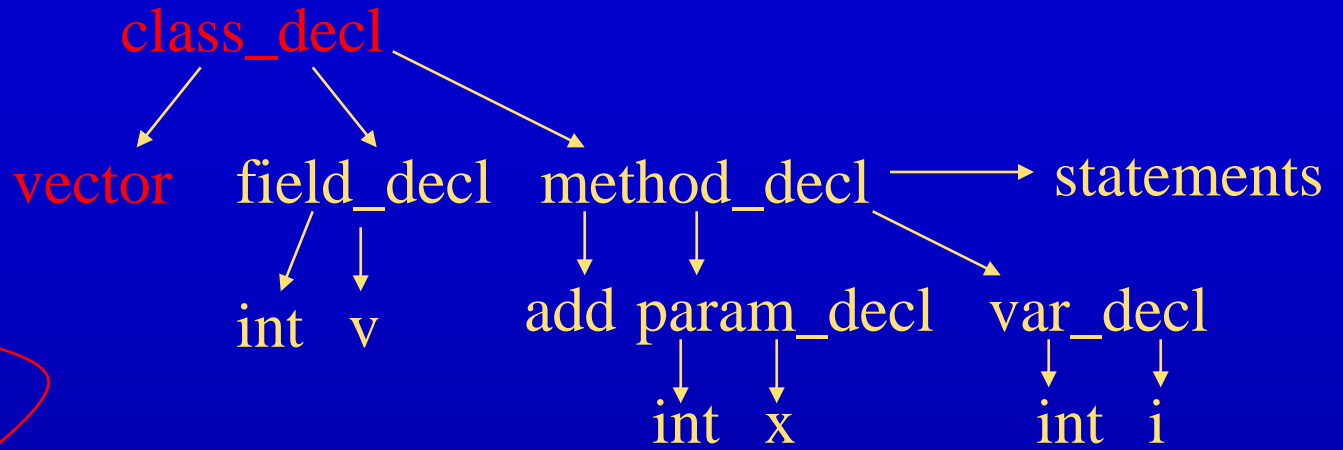

Intermediate Representation for Classes

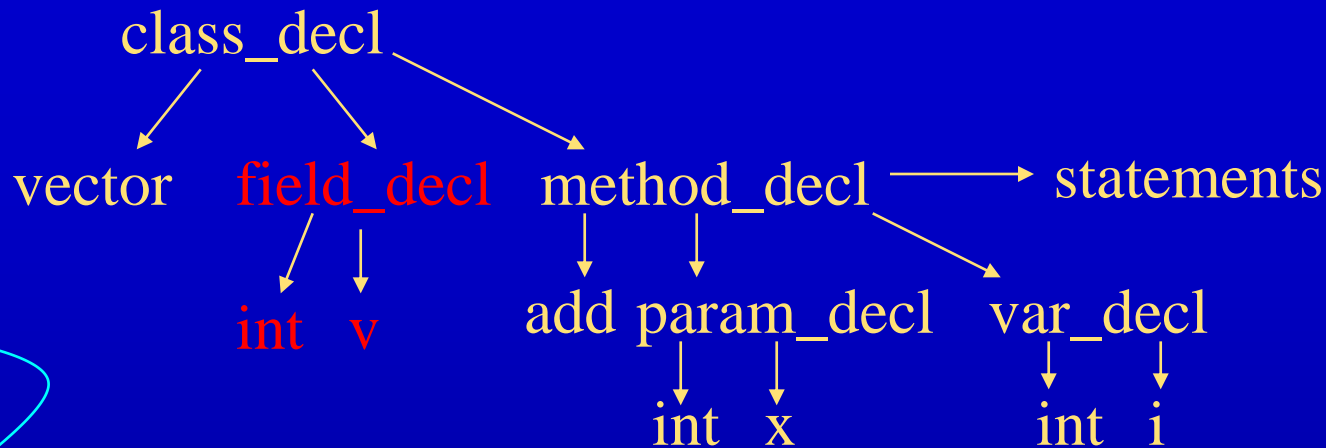

```
class vector {  
    int v[];  
    void add(int x) {  
        int i; i = 0;  
        while (i < v.length) { v[i] = v[i]+x; i = i+1; }  
    }  
}
```

class symbol
table

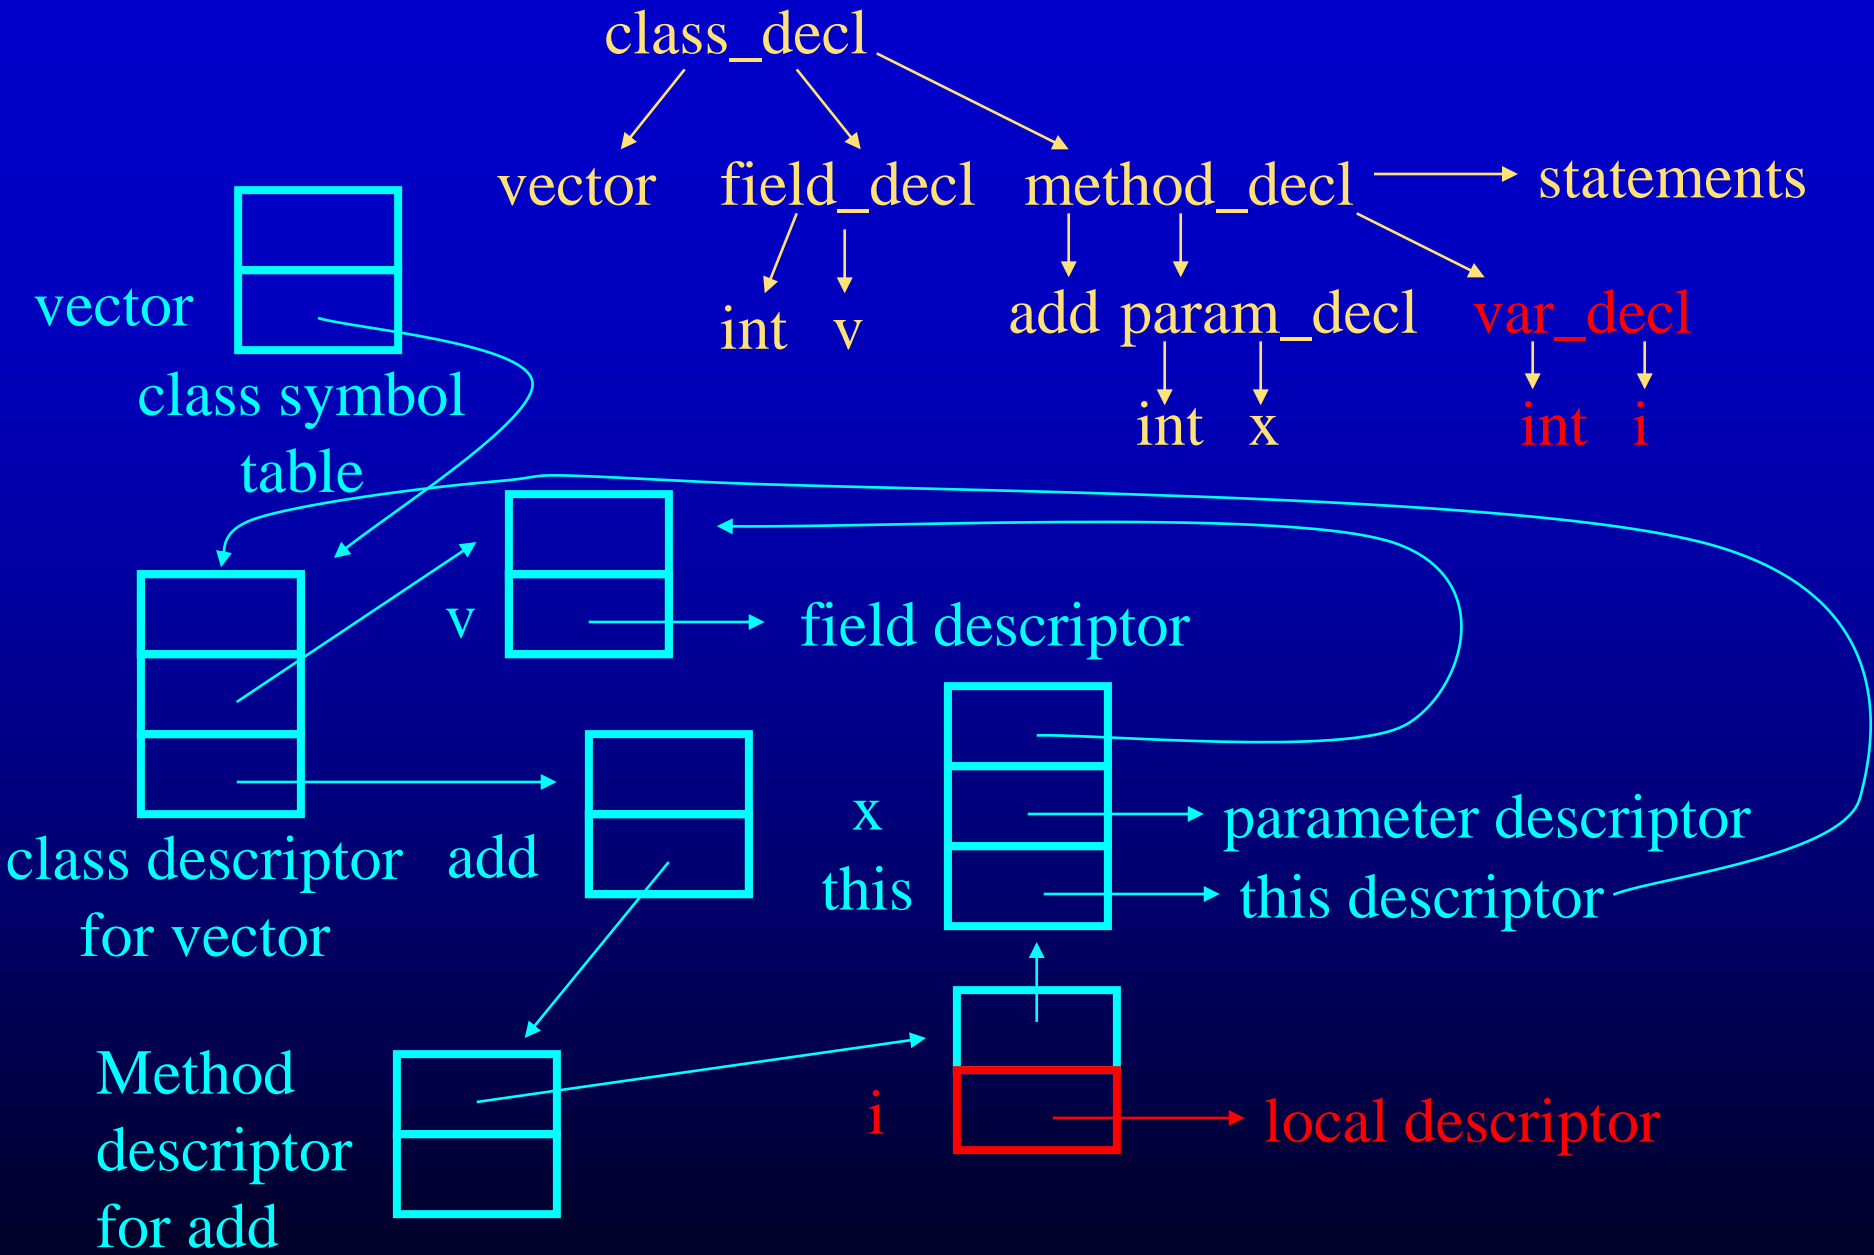

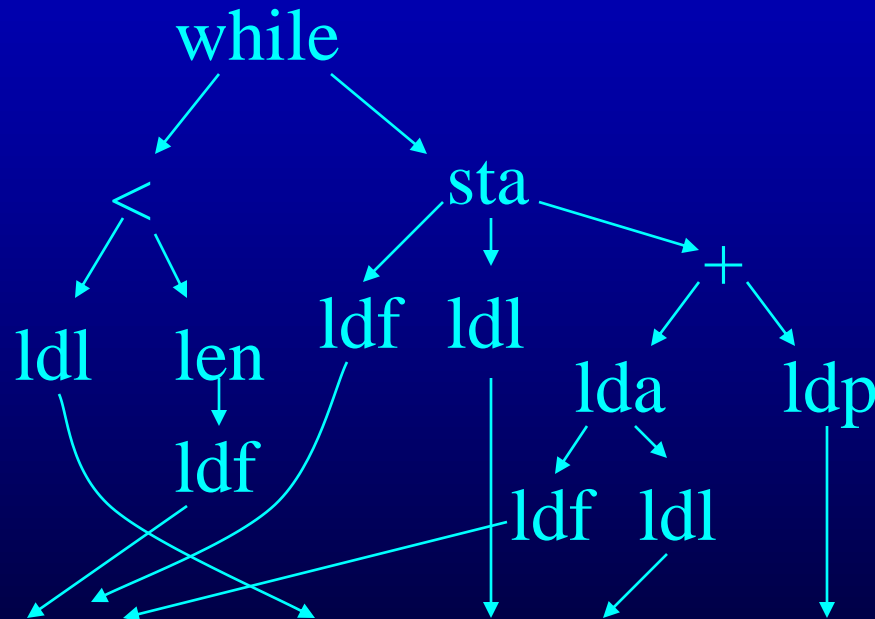

Intermediate Representation for Code

while (i < v.length)

v[i] = v[i]+x;

field descriptor for v local descriptor for i parameter descriptor for x

```
while (i < v.length)
    v[i] = v[i]+x;
```

field descriptor for v local descriptor for i parameter descriptor for x

```
while (i < v.length)
    v[i] = v[i]+x;
```

ldl

field descriptor for v local descriptor for i parameter descriptor for x

```
while (i < v.length)
```

```
    v[i] = v[i]+x;
```

ldl

ldf

field descriptor for v local descriptor for i parameter descriptor for x

```
while (i < v.length)
```

```
v[i] = v[i]+x;
```

field descriptor for v local descriptor for i parameter descriptor for x

```
while (i < v.length)
```

```
    v[i] = v[i]+x;
```

field descriptor for v local descriptor for i parameter descriptor for x

```
while (i < v.length)
```

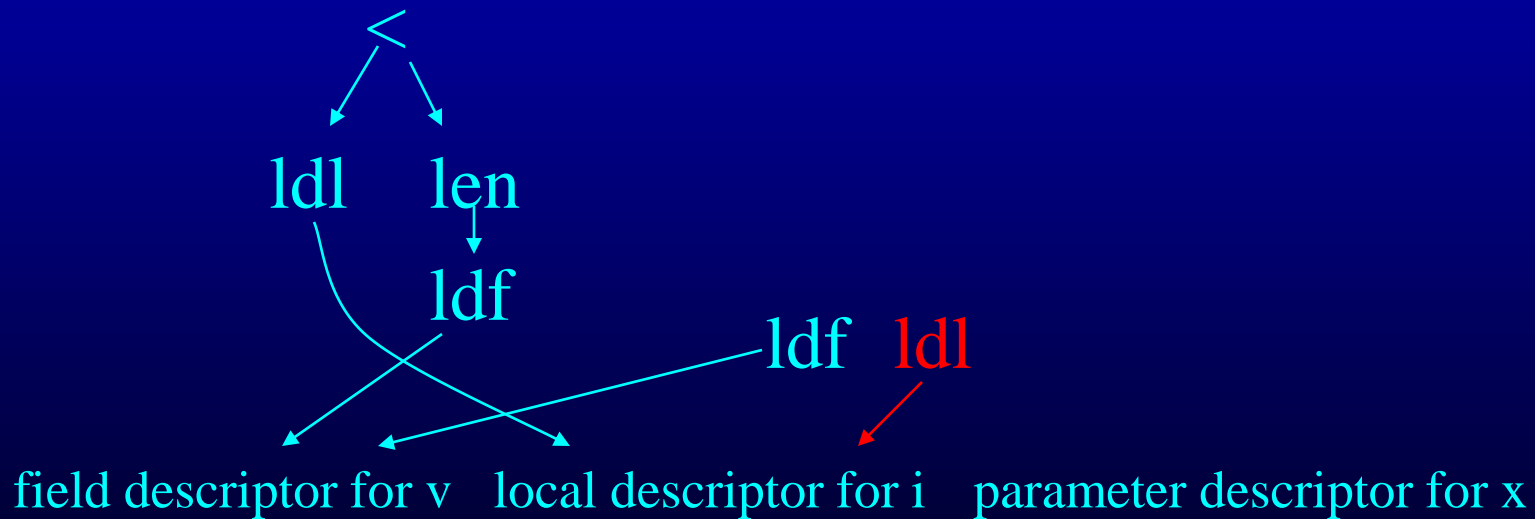

```
  v[i] = v[i]+x;
```

field descriptor for v local descriptor for i parameter descriptor for x

```
while (i < v.length)
```

```
  v[i] = v[i]+x;
```

while (i < v.length)

v[i] = v[i]+x;

field descriptor for v local descriptor for i parameter descriptor for x

while (i < v.length)

v[i] = v[i]+x;

field descriptor for v local descriptor for i parameter descriptor for x

while (i < v.length)

v[i] = v[i] + x;

field descriptor for v local descriptor for i parameter descriptor for x

while (i < v.length)

v[i] = v[i]+x;

field descriptor for v local descriptor for i parameter descriptor for x

while (i < v.length)

v[i] = v[i]+x;

field descriptor for v local descriptor for i parameter descriptor for x

while (i < v.length)

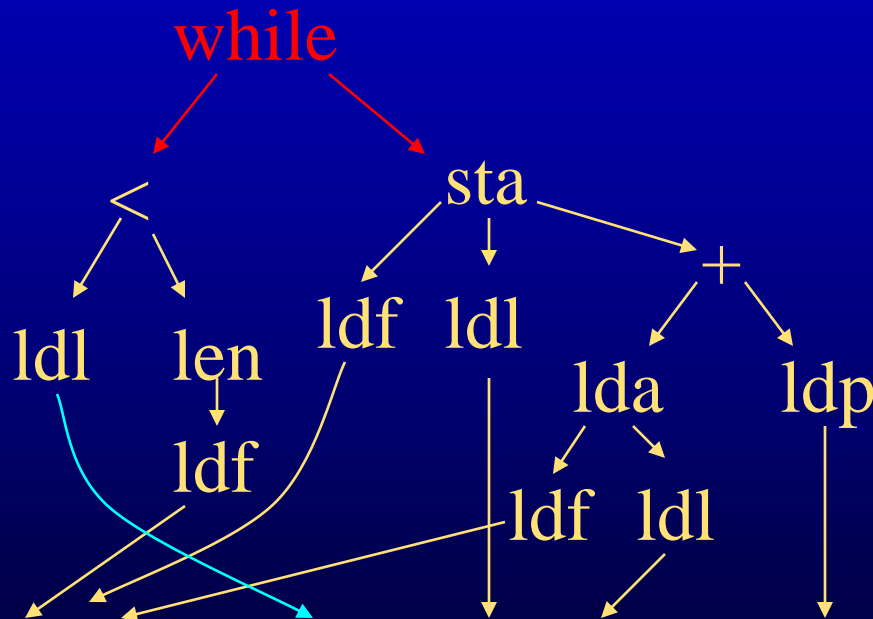

v[i] = v[i]+x;

field descriptor for v local descriptor for i parameter descriptor for x

while (i < v.length)

v[i] = v[i]+x;

field descriptor for v local descriptor for i parameter descriptor for x

while (i < v.length)

v[i] = v[i]+x;

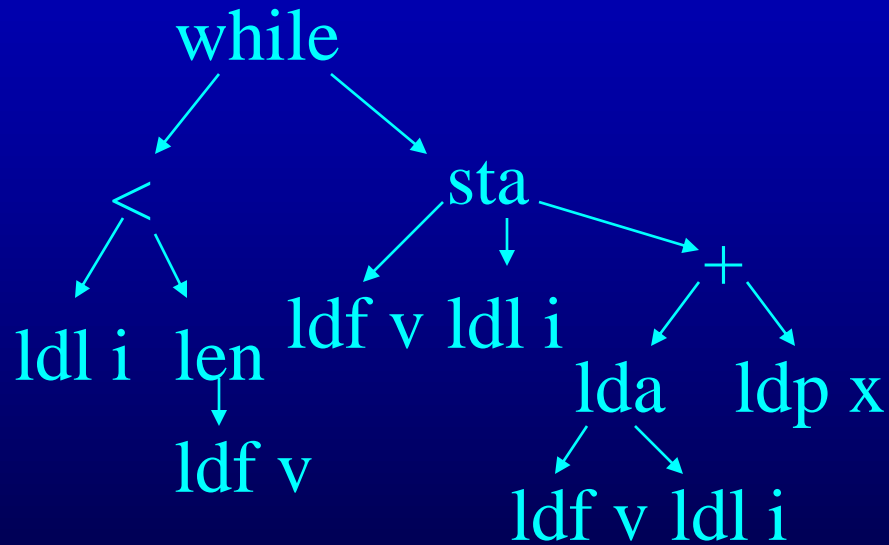

field descriptor for v local descriptor for i parameter descriptor for x

Abbreviated Notation

while (i < v.length)

v[i] = v[i]+x;

Parameter Descriptors

- When build parameter descriptor, have
 - name of type
 - name of parameter
- What is the check? Must make sure name of type identifies a valid type
 - look up name in type symbol table
 - if not there, look up name in program symbol table (might be a class type)
 - if not there, fails semantic check

Local Descriptors

- When build local descriptor, have
 - name of type
 - name of local
- What is the check? Must make sure name of type identifies a valid type
 - look up name in type symbol table
 - if not there, look up name in program symbol table (might be a class type)
 - if not there, fails semantic check

Local Symbol Table

- When build local symbol table, have a list of local descriptors
- What to check for?
 - duplicate variable names
 - shadowed variable names
- When to check?
 - when insert descriptor into local symbol table
- Parameter and field symbol tables similar

Class Descriptor

- When build class descriptor, have
 - class name and name of superclass
 - field symbol table
 - method symbol table
- What to check?
 - Superclass name corresponds to actual class
 - No name clashes between field names of subclass and superclasses
 - Overridden methods match parameters and return type declarations of superclass

Load Instruction

- What does compiler have? Variable name.
- What does it do? Look up variable name.
 - If in local symbol table, reference local descriptor
 - If in parameter symbol table, reference parameter descriptor
 - If in field symbol table, reference field descriptor
 - If not found, semantic error

Load Array Instruction

- What does compiler have?
 - Variable name
 - Array index expression
- What does compiler do?
 - Look up variable name (if not there, semantic error)
 - Check type of expression (if not integer, semantic error)

Add Operations

- What does compiler have?
 - two expressions
- What can go wrong?
 - expressions have wrong type
 - must both be integers (for example)
- So compiler checks type of expressions
 - load instructions record type of accessed variable
 - operations record type of produced expression
 - so just check types, if wrong, semantic error

Type Inference for Add Operations

- Most languages let you add floats, ints, doubles
- What are issues?
 - Types of result of add operation
 - Coercions on operands of add operation
- Standard rules usually apply
 - If add an int and a float, coerce the int to a float, do the add with the floats, and the result is a float.
 - If add a float and a double, coerce the float to a double, do the add with the doubles, result is double

Add Rules

- Basic Principle: Hierarchy of number types (int, then float, then double)
- All coercions go up hierarchy
 - int to float; int, float to double
- Result is type of operand highest up in hierarchy
 - int + float is float, int + double is double, float + double is double
- Interesting oddity: C converts float procedure arguments to doubles. Why?

Type Inference

- Infer types without explicit type declarations
- Add is very restricted case of type inference
- Big topic in recent programming language research
 - How many type declarations can you omit?
 - Tied to polymorphism

Equality Expressions

- If build expression $A = B$, must check compatibility
- B must be compatible with A
 - Can always substitute a B for an A
 - B satisfies all the requirements for an A
 - B can do at least as much as A
- Int compatible with Int
- Float compatible with Int, Int compatible with Float
- Class D compatible with Class C if D inherits from C (but not vice-versa)

Inheritance Example - Point Class

```
class point {  
    int c;  
    int getColor() { return(c); }  
    int distance() { return(0); }  
}
```

Point Subclasses

```
class cartesianPoint extends point{  
    int x, y;  
    int distance() { return(x*x + y*y); }  
}
```

```
class polarPoint extends point {  
    int r, t;  
    int distance() { return(r*r); }  
    int angle() { return(t); }  
}
```

Object Interfaces

- Point - getColor(); distance();
 - CartesianPoint – getColor(); distance();
 - PolarPoint – getColor(); distance(); angle();
 - Semantic check
 - Use type declarations
 - Check that object implements every invoked method
- ```
Point p = new PolarPoint();
p.distance(); // checks
p.angle(); // does not check
```

# Legal and Illegal Code Sequences

- Legal code sequences
  - `Point p = new Point(); p.distance();`
  - `Point p = new CartesianPoint(); p.distance();`
  - `PolarPoint o = new PolarPoint(); o.angle();`
  - `Point p; PolarPoint o; p = o;`
- Illegal code sequences
  - `Point p = new PolarPoint(); p.angle();`
  - `Point p; PolarPoint o; o = p;`

# Store Instruction

- What does compiler have?
  - Variable name
  - Expression
- What does it do?
  - Look up variable name.
    - If in local symbol table, reference local descriptor
    - If in parameter symbol table, error
    - If in field symbol table, reference field descriptor
    - If not found, semantic error
  - Check type of variable name against type of expression
    - If variable type not compatible with expression type, error

# Store Array Instruction

- What does compiler have?
  - Variable name, array index expression
  - Expression
- What does it do?
  - Look up variable name.
    - If in local symbol table, reference local descriptor
    - If in parameter symbol table, error
    - If in field symbol table, reference field descriptor
    - If not found, semantic error
  - Check that type of array index expression is integer
  - Check type of variable name against type of expression
    - If variable element type not compatible with expression type, error

# Method Invocations

- What does compiler have?
  - method name, receiver expression, actual parameters
- Checks:
  - receiver expression is class type
  - method name is defined in receiver's class type
  - types of actual parameters match types of formal parameters
  - What does match mean?
    - same type?
    - compatible type?

# Semantic Check Summary

- Do semantic checks when build IR
- Many correspond to making sure entities are there to build correct IR
- Others correspond to simple sanity checks
- Each language has a list that must be checked
- Can flag many potential errors at compile time
